# Department of Computer Science National Tsing Hua University EECS403000 Computer Architecture

Spring 2024, Homework 2 Due date: **April 11, 2024 23:59 pm** 

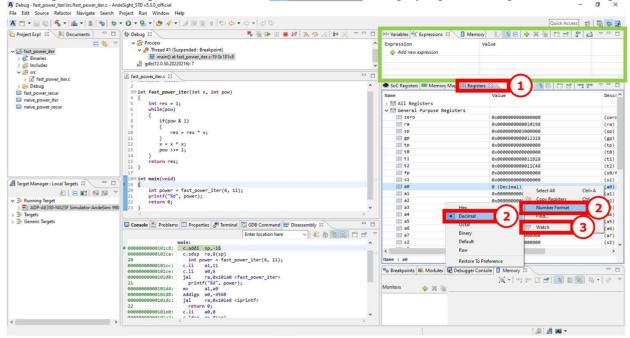

To inspect the Assembly code of the program, follow the steps below.

- (1) Build the program with the Debug configuration.
- (2) Start debugging \* the desired program as an Application Program.
- (3) Navigate to the Disassembly view to examine the generated assembly code.
- (4) To insert breakpoints, double-click on the Assembly code or the corresponding C code lines on the left.
- (5) Press Resume in the debug window to proceed to the next breakpoint.

To observe register value changes, Start Debugging \* as an Application Program and follow the steps:

- (1) Access the Registers tab and expand the General Purpose Registers section to view their current values.
- (2) Customize the Number format by right-clicking a register and choosing the desired format.
- (3) Add a register to the Expressions tab for convenient monitoring by right-clicking it and selecting Watch.

### 1. (35 points)

This question explores the fast power algorithm implemented in two ways (iterative and recursive) using AndeSight<sup>TM</sup> with the setup similar to Homework 1. We will analyze the source code for <code>fast\_power\_iter.c</code> and <code>fast\_power\_recur.c</code>. The default optimization level is -Og by default unless stated otherwise. For each question, attach screenshots of AndeSight<sup>TM</sup> to support your answer. No points will be given if the screenshot is missing. Hint: Use the "Debug" button in the toolbar and carefully insert breakpoints in between instructions. Press the "Resume" button in the debug window to move to the next breakpoint. You can also refer to the RISC-V Specs document if you encounter some difficulty understanding the Assembly code generated by AndeSight<sup>TM</sup>.

## (a) (5 points) RISC-V Calling Convention

Compilers typically translate functions into subroutine and perform function calls using a jump instruction following a calling convention. While function calls can be inefficient, they are essential in programming. Locate the starting and ending memory addresses of the code memory allocated to the <code>fast\_power\_recur</code> and <code>fast\_power\_iter</code> subroutines by examining the Assembly code. Identify how these subroutines are called within main and write them down in the Reference field in the table.

Subroutine	Starting memory address	Ending memory address	Reference
fast_power_recur	0000000000104a8	0000000000104e0	<pre>jal ra,0x104a8 <fast_power_recur></fast_power_recur></pre>
fast_power_iter	0000000000104a8	0000000000104c4	jal ra,0x104a8 <fast iter="" power=""></fast>

### (b) (10 points) RISC-V Calling Convention

The RISC-V calling convention requires the callee to preserve the values of specific registers across function calls. Examine the Assembly code for <code>fast\_power\_recur</code> function. Find and record the instructions (and the memory locations) that save these registers. Extend the table below to show how these instructions affect the stack. Include the saved register names and corresponding stack offsets. Order the table by the increasing order of stack offset.

Code memory address	Instruction	Saved register	Stack offset
000000000010466	c.sdsp s1,8(sp)	s1	8
000000000010464	c.sdsp s0,16(sp)	s0	16
0000000000104b2	c.sdsp ra,24(sp)	ra	24

```

## (c) (10 points) Effects of the compiler on RISC-V Assembly Code

To make common cases fast, compilers can allocate application program variable to processor registers, which are much faster than memory. Compile both <code>fast\_power\_iter</code> and <code>fast\_power\_recur</code> functions with -O0 optimization flag and answer the following questions:

- (i) Just before jumping to the corresponding subroutine from main, which registers hold the parameters **x** and **pow**, and what values do they contain?
- (ii) Immediately after returning from the subroutine (i.e. just before the next instruction after the jump), which register stores the return value, and what is its value?

Function	Param	eter <b>x</b>	Paramet	ter <b>pow</b>	Return value		
Tunction	Register	Value	Register	Value	Register	Value	
fast_power_iter	a0	6	a1	11	a0	362797056	
fast_power_recur	a0	6	a1	11	<b>a</b> 0	362797056	

```

### (d) (10 points) Effects of great ideas on performance

Pipeline execution and parallelization are two key techniques for enhancing performance. Consider <code>fast\_power\_iter.c</code> and disregard overheads from parallelization and data transmission. Here's an approach for pipelined execution and parallelization using three cores and a two-stage pipeline. Assume that each core fetches and executes the instructions sequentially.

Core A (Pipeline Stage 1): Calculates  $\mathbf{x} \leftarrow \mathbf{x} \star \mathbf{x}$ , and passes the new  $\mathbf{x}$  to Core C.

Core B (Pipeline Stage 1): Calculates pow ← pow >> 1, and passes the new pow to Core C.

Core C (Pipeline Stage 2): Checks if pow is zero. If true, execute a jump and there is nothing left to do. Otherwise, it calculates res  $\leftarrow$  res \* x if pow is odd, where res and pow are results from Core A and Core B in the previous cycle.

	Time axis $\rightarrow$									
Core A & B	Core C									
	Core A & B	Core C								
		Core A & B	Core C							
			Core A & B	Core C						
				Core A & B	Core C					
					Core A & B	Core C				
						Core A & B				
							•••			

In other words, Cores A and B operate in parallel, while Core C processes their results in a pipeline fashion. Analyze the code of **fast\_power\_iter** function in **fast\_power\_iter.c**, identify the instructions for each core, and record their cycle counts. Explain whether achieving a speedup of 2 for the pipelined parallelized function is possible.

```

假設做了 n 次 Core A, Core B, Core C, 原本需要 (4+1+6)\*n cycle counts, 優化後變成需要 4+6\*n cycle counts, ((4+1+6)\*n)/(4+6\*n) = 11\*n/(4+6\*n) < 2, 因此不可能。

# 2. (30 points) RISC-V Assembly Code

Consider a little-endian 64-bit RISC-V sequential processor with the following contents in the register set, data memory, and code memory. Assume that the current PC has the value 0x0000 0000 0001 00B0.

Reg.	Iı	nitial v	alue		Reg.	I	nitial v	alue		Memory address			Initial value

(a) (5 points) Decode instructions with instruction IDs 5, 6, and 8. Then, briefly explain their functionalities.

(5 points) L	5 points) becode instructions with instruction 1155 5, 6, and 6. Then, otherly explain their ranetionalities.						
Instruction ID	Hexadecimal Encoded instruction	Decoded instruction and brief explanation					
5	0x0040 8067	jalr x0,4(x1) 跳回 x1+4 那個 address 存的指令 然後將下一行的 address 放進 x0 (但 x0 永遠為 0)					
6	0xFF84 3283	ld x5,-8(x8) 將 x8-8 所存的 double word load 進 x5					
8	0x4142 D293	srai x5,x5,20 將 x5 做算術右移 20 位					

(b) (15 points) Trace the execution flow of the assembly code. Extend the table below. For each executed instruction, record its ID, any updated registers and/or memory cells, and their new values (if any) in hexadecimal representation. Annotate updated memory values per 32-bit word. The first three instructions have been completed for you.

Instruction ID	Updated register	Updated memory					
1	x7 <- x5-x6 = 0x0000 0000 0000 0004						
2		MEM[0x0000 003E FF20 13F0] <- 0xFF20 13E0 MEM[0x0000 003E FF20 13F4] <- 0x0000 003E					
3	x1 <- PC+4 = 0x0000 0000 0001 00BC						
6	x5 < -8(x8) = 0x0A0B 0130 0041 0000						
7	x5 < -x5&x30 = 0x0000 0000 0040 0000						
8	x5 <- x5<<20 = 0x0000 0000 0000 0004						
9							
10	x28 <- x0+x2 = 0x0000 003E FF20 13E0						
11	x7 <- 10(x28) 0xFFFF FFFF FFFF FF91						
12							
13	x1 <- PC+4 = 0x0000 0000 0001 00E4						
4	x6 <- 4(x2) = 0xFFFF FFFF A800 3F10						
5							
15	x7 <- x6^x7 = 0x0000 0000 57FF C081						
16	x7 <- x7>>16 = 0x0000 0000 0000 57FF						
17	x31 <- x6+1000 = 0xFFFF FFFF A800 42F8						
18	x31 <- x31>>16 = 0xFFFF FFFF FFFF A800						
19		MEM[0x0000 003E FF20 13F8] <- 0x0041 0004					
20		MEM[0x0000 003E FF20 13E4] <- 0xFFFF A800 MEM[0x0000 003E FF20 13E8] <- 0xFFFF FFFF					

<sup>(</sup>c) (5 points) Once you have completed the execution flow table, count the total number of memory accesses (excluding register accesses) performed throughout the code.

(d) (5 points) Suppose you want to insert an instruction after instruction ID 20. This instruction should use a **blt** to jump to the label **BEGIN** if the value in register **x31** is less than **x7**. Complete the table below with the instruction. Show how you convert the Assembly instruction into its hexadecimal representation. Moreover, will the branch be taken?

Code address	Assembly instruction	Hexadecimal encoded instruction	Taken?
0x0000 0000 0001 0100	blt x31,x7,BEGIN	0xFC7FC2E3	Yes

opcode: 1100011

imm[4:1,11]: 00101

func3: 100
rs1: 11111
rs2: 00111

imm[12,10:5]: 1 111110 (imm: 1 1111 1100 0100)

instruction: 1 111110 00111 11111 100 0010 1 1100011

## 3. (10 points) RISC-VAssembly to C

Translate the following RISC-V Assembly code to the equivalent C code. Indicate the corresponding C code for each line of Assembly. Assume that variables, m, i, j, and total are stored in registers x3, x10, x11, and x12, respectively. MemArray is an array (consisting of 4-byte integers as its elements) with its base address stored in register x13.

```
addi x10, x0, 0
     addi x28, x13, 0
LOOPI:
     bge x10, x3, ENDI
     addi x11, x0, 0
     addi x12, x0, 0
     lw x29, 0(x28)
     addi x30, x0, 32
LOOPJ:
     bge x11, x30, ENDJ
     srl x31, x29, x11
     andi x31, x31, 1
     add x12, x12, x31
     addi x11, x11, 1
     jal x0, LOOPJ
ENDJ:
     sw x12, 0(x28)
     addi x10, x10, 1
     addi x28, x28, 4
     jal x0, LOOPI
ENDI:
```

```
addi x10, x0, 0
                                   i = 0
                               1
 1
         addi x28, x13, 0
 2
                               2
                                   // set x28 point to MemArray[0]
        bge x10, x3, ENDI
                               3
                                   while (i < m) {
 3
         addi x11, x0, 0
                               4
 4
                                       j = 0;
         addi x12, x0, 0
                               5
 5
                                       total = 0;
 6
         lw x29, 0(x28)
                               6
                                       // load MemArray[i] to x29
 7
         addi x30, x0, 32
                               7
                                       // set x30 = 32
    LOOPJ:
        bge x11, x30, ENDJ
                               8
                                       while (j < 32) {
 8
 9
         srl x31, x29, x11
                                           unsigned int tmp = MemArray[i];
                               9
                                           // 因為是 srl 所以要先存成 unsigned, tmp >> j
         andi x31, x31, 1
                              10
                                           // (tmp >> j) & 1
10
         add x12, x12, x31
11
                              11
                                           total += (tmp >> j) & 1;
         addi x11, x11, 1
12
                              12
                                           j++;
13
         jal x0, LOOPJ
                              13
    ENDJ:
14
         sw x12, 0(x28)
                              14
                                       MemArray[i] = total;
         addi x10, x10, 1
                              15
15
                                       i++;
         addi x28, x28, 4
                                       // 同為上一行的 i++
16
                              16
17
         jal x0, LOOPI
                              17
                                   }
    ENDI:
```

### 4. (10 points) C to RISC-VAssembly

For the following C statement, write the corresponding RISC-V Assembly code. Assume that the base addresses of arrays **A** and **B** are in registers **x5** and **x6**, respectively, and the variables **i** and **j** are assigned to registers **x7** and **x11**, respectively.

$$j = B[A[i*4 + 1]] + B[i]$$

(a) (5 points) Assume that the elements of the arrays **A** and **B** are 4-byte words.

```
# 將 x28 設成 i*4
slli x28,x7,2
add x29,x28,x6
                 # 將 x29 指到 B[i]
                # 將 B[i] load 進 x31
lw
    x31,0(x29)
                 # 將 x28 設成 (i*4) + 1
addi x28,x28,1
                 # 因為是 4-byte word,所以將 x28 * 4 算出 offset
slli x28,x28,2
add x28,x28,x5
                # 將 x28 指到 A[i*4 + 1]
                 # 將 A[i*4 + 1] load 進 x29
    x29,0(x28)
                 # 因為是 4-byte word, 所以將 x29 * 4 算出 offset
slli x29,x29,2
                # 將 x29 指到 B[A[i*4 + 1]]
add x29,x29,x6
    x30,0(x29)
                 # 將 B[A[i*4 + 1]] load 進 x30
lw
                # 將 x11 設成 B[A[i*4 + 1]] + B[i]
add x11,x30,x31
```

(b) (5 points) Assume that the elements of the arrays **A** and **B** are 8-byte words.

```
slli x28,x7,2
                # 將 x28 設成 i*4
addi x28,x28,1
                # 將 x28 設成 i*4 + 1
                # 因為是 8-byte word,所以將 x28 * 8 算出 offset
slli x28,x28,3
add x28,x28,x5
                # 將 x28 指到 A[i*4 + 1]
ld
    x29,0(x28)
                # 將 A[i*4 + 1] load 進 x29
slli x29,x29,3
                # 因為是 8-byte word,所以將 x29 * 8 算出 offset
slli x28,x7,3
                # 因為是 8-byte word,所以將 x7 * 8 算出 offset
add x29,x29,x6
                # 將 x29 指到 B[A[i*4 + 1]]
                # 將 x28 指到 B[i]
add x28,x28,x6
ld x30,0(x29)
                # 將 B[A[i*4 + 1]] load 進 x30
                # 將 B[i] load 進 x31
ld
    x31,0(x28)
add x11,x30,x31 # 將 x11 設成 B[A[i*4 + 1]] + B[i]
```

### 5. (15 points) RISC-V Calling Convention

Implement the following C code in RISC-V Assembly. Note the RISC-V Spec: "In the standard RISC-V calling convention, the stack grows downward and the stack pointer is always kept 16-byte aligned." Moreover, write down comments to describe the Assembly code clearly.

```
Moreover, write down comments to describe the Assembly code clearly.
long long int Func(int n)
      \{ if (n == 0) \}
          return 0;
     }
     if ((n & 1) != 0) {
          return n + Func(n >> 1);
      } else {
          return Func(n >> 1);
     }
}
Func:
                      # 將 sp 往下移 16
   addi sp,sp,-16
                      # 把 x1 的值存進 8(sp)
    sd
        x1,8(sp)
        x10,0(sp)
                      # 把 n 的值存進 0(sp)
    sd
        x10,x0,Odd
                      # 若 n != 0 則跳至 Odd
   bne
   addi x10,x0,0
                      # 將 x10 設成 0
    addi sp,sp,16
                      # 將 sp 往上移 16
    jalr x0,0(x1)
                      # return 回去上一層 function
Odd:
   andi x28,x10,1
                      # x28 <- n & 1
   beq x28,x0,Even
                      # 若 (n & 1) == 0 則跳到 Even
    srai x10,x10,1
                      # x10 <- n >> 1
                      # 呼叫 Func(n >> 1)
    jal x1,Func
                      # 將 0(sp) 的值 load 到 x29 (原本這層 n 的值)
        x29,0(sp)
    ld
                      # 將 8(sp) 的值 load 回 x1 (以 return 回正確的地方)
    ld
        x1,8(sp)
   add x10,x10,x29
                      # 將 return value 設成 n + Func(n >> 1)
    addi sp, sp, 16
                      # 將 sp 往上移 16
                      # return 回去上一層 function
    jalr X0,0(x1)
```

#### Even:

```
srai x10,x10,1  # x10 <- n >> 1
jal x1,Func  # 呼叫 Func(n >> 1)
ld x1,8(sp)  # 將 8(sp) 的值 load 回 x1 (以 return 回正確的地方)
addi sp,sp,16  # 將 sp 往上移 16
jalr x0,0(x1)  # return 回去上一層 function
```
